Medical Identity Card (KIB) is a patient identity card that is used to obtain health services, mainly used to provide medical records when registering. The study design uses descriptive analysis with a qualitative approach. The sampling technique used is Saturated Sampling. The population in this study were all medical records officers of the patient registration section, amounting to 2 people, the sample taken was 10 medical record files The results showed that the use of MNH was less than the maximum and the provision of medical record files obtained were 4 late medical record files (40%) , 3 timely documents (30%), and 3 medical record files that are less than 10 minutes (30%). While the factors on the use of MNH are the lack of evaluation of patients and evaluation of patient registration officers.
