Title : Factors causing the occurrence of population deaths  
Indonesia suffering from cervical cancer in 2014-2017*

*Cervical cancer is a type of malignant tumor that affects the surface layer epithelium of the cervix. Cervical cancer is the number two cause of death in the world in women of all existing cancers. Eighty percent of them are in developing countries like Indonesia. This study aims to determine the factors that cause the death of Indonesian people suffering from cervical cancer in 2014-2017. Data and information collection techniques carried out in this study are library studies with systematic review method that uses previous health journals related to cervical cancer in 2014-2017 from literature obtained through the internet. Data analysis used is a qualitative descriptive technique using narration or words. The results of the study show that the factors that cause cervical cancer in 2014-2017 are human papilloma virus, smoking, vaginal discharge, parity/number of children, age at first marriage, sexual partners, hereditary/family history, birth control pills/contraception, food, education and employment. It is recommended for Indonesian residents to always pay attention to their health, especially women who already have risk factors for cervical cancer by following an early cervical cancer prevention program in health services.*
