**ABSTRACT**

Gastroenteritis is a common disease in infants and children. In infants and children, gastroenteritis is defined as stool expenditure  $> 10 \text{ g / kg / 24h}$ . Based on the percentage of disease at IKA II Gatot Soebroto Army Hospital, Central Jakarta 2018, gastroenteritis occupies the fourth most disease sequence. In this case study used the method of nursing process approach with 5 children who suffer from gastroenteritis at children ward Gatot Soebroto Army Hospital. 5 children with gastroenteritis were in the age group of 0-5 years (60%) and school age 5-11 years (40%), 3 boys (60%) and 2 girls (40%), 5 children (100%) were caused by infection. The assessment, nursing diagnoses and nursing orders were adjusted to the related theories, whereas the implementation and evaluation were performed based on the intervention and the action given. In this nursing care, an imbalance between intake and output, (100%) experience excessive fluid output compared to intake, in which case the authors suggest that nurses may work with families in increasing fluid intake by controlling intake and output in children with dehydrated gastroenteritis.
